

Problema A **Region**

Arquivo fonte: region.{ c | cpp | java | py }
Autor: Prof. Me. Sérgio Luiz Banin (Fatec São Paulo)

Donald Harris is an american entrepreneur beginning business in Brazil. He is famous due to his chain of stores that provides in-person service at several addresses and makes home deliveries regardless of the purchase value.

The only restriction on his delivery system is that the address must be within a region close to one of the physical stores in his network. Upon his arrival in Brazil, he learned about the CEP code system used by the brazilian company Correios and determined that a survey be carried out to determine which CEP codes would be considered for each store.

Now that work is done and he needs a computer program that can determine whether a customer's address is within a service region or not, and you, lucky guy, have been hired to develop it.

Input

The input consists of a test case, the first line of which contains an integer QR ($0 < QR \le 100$) that defines the number of regions served by a store. Next, there are QR lines containing two valid CEP codes according to the Brazilian standard. This section is not supposed to be ordered in any way.

The next line contains an integer Q ($0 < QR \le 1000$) that represents the number of delivery requests, followed by Q lines containing the customer's CEP code, according to the Brazilian standard. This section is also not ordered.

It is ensured that all the CEP codes in the input are in a valid format.

Output

The program should provide information for each customer's CEP code about whether or not they are served by the delivery system.

First, the output should contain, in ascending order, the list of customer CEP codes served by the delivery system in a format consisting of the CEP code number followed by the phrase *is served by our delivery system* (in lowercase letters).

Then, the unserved CEP codes should be listed, in ascending order, in a similar format with the CEP code followed by the phrase *is not served by our delivery system* (in lowercase letters).

Don't forget the newline character at the end of each line.
